ABSTRACT:
Gold nanoparticles have many properties that are attractive for the use in the cancer therapy. They are small and widely penetrate into the body, preferentially accumulating at the tumor sites owing to EPR effect. They can bind many proteins and drugs and can be actively targeted to cancer cells over expressing cell surface receptors. Gold nanoparticle have high atomic number, which leads to greater absorption of kilovoltage X-rays and provide greater contrasts than standard agents. Gold nanoparticles have been shown to cause radio sensitization at kilovoltage and megavoltage photon energies. The factors that affect gold nanoparticle pharmacokinetics, bio-distribution and in-vivo toxicity need to be clarified. Targeted gold nanoparticle need to exit tumour vasculature, cross the tumour intersitium, enter the cells and potentially exit lysosomes to be effective in-vivo. A standard approach for physicochemical characterization and pre-clinical testing needs to be implemented and this process is being aided by the NLC. With intense global interest in nanotechnology and particularly in nanomedicine.

Key words: Gold nanoparticles, EPR effect, Tumour, PEGylation, Targeting.

INTRODUCTION
Nanoparticles[1]
Nanoparticles have several biomedical and industrial applications in diagnosis of disease targeted chemotherapy and in drug delivery. Multi functionality and sub micronic size is the main characteristics of nanoparticles can be integrated with ligands, imaging labels, therapeutic agents and other functionalities for site specific drug delivery and cellular uptake. In the present review we are discussing the application (Fig. 1) and synthesis of gold nanoparticles which is the most studied among all metallo-nanoparticles.

Various anticancer drugs are available but these are cause the necrosis of cancerous cell as well as normal cells. But gold nanoparticles cause the necrosis of only cancer cells. These are targeted drug delivery systems which are smaller than human cells so can easily penetrate the tumour and destroy the cancerous cell. Various anti cancer drugs
conjugated with gold nanoparticles result in increased efficiency of anticancer drug. Gold nanoparticles are beneficial for chemotherapy and also for diagnosis of cancer.

History of Nanoparticles
The historical development of nanoparticles starting with Paul Ehrlich and then first attempts by Ursula Scheffel and colleagues and the extensive work by the group of professor Peter Speiser at the ETH Zurich in the late 1960s and early 1970s are described from a personal point of view. Nanoparticles for the delivery of drugs across the blood brain barrier (BBB) and PEGylated nanoparticles with a prolonged blood circulation time.

Types of Nanoparticles
1. Magnetic Nanoparticles
2. Metallic Nanoparticles

Magnetic Nanoparticles
Magnetic nanoparticles are a class of nanoparticles which can be manipulated using magnetic field, because they possess attractive properties which could see potential use in catalyst, biomedicine, magnetic resonance imaging, data storage. Such particles containing iron, nickel and cobalt and their chemical compounds. While nanoparticles are smaller than 1 micrometer in diameter (typically 5-500 nanometers), the larger microbeads are 0.5-500 micrometer in diameter.

Types of Magnetic Nanoparticles
1. Oxides: Ferrite
2. Metallic
3. Metallic with a shell

Metallic Nanoparticles
Today these materials can be synthesized and modified with various chemical functional groups which allow them to be conjugated with antibodies, ligands. In addition to various imaging techniques in tandem newer multifunctional nanoshells and nanocages have been developed. Thus in this review article, we aim to provide an introduction to magnetic nanoparticles, gold nanoparticles, nanoshells and nanocages, and silver particles followed by their synthesis, physicochemical properties.

Types of Metallic Nanoparticles
1. Iron oxide nanoparticle
2. Nanoshell & nanocages
3. Silver nanoparticles
4. Gold nanoparticles

GOLD NANOPARTICLES
Gold nanoparticles have gained increasing interest due to their special features, such as an unusual optical and electronic properties, high stability and biological compatibility, controllable morphology and size dispersion and easy surface functionalization. In typical synthesis AuNPs are produced by reduction of gold salts in appropriate solvents. After synthesis the stabilising agent surrounding the AuNPs can be replaced by other molecules by ligand exchange reactions. Functionalisation of AuNPs makes it possible to adjust the surface properties and attach different kinds of molecules to the particles. AuNPs have shown the great potential applications in the fields of chemistry, physics, biology and medicine. The exciting finding is that AuNPs have shown a great potential in therapies for HIV. They have stopped HIV from infecting human white blood cells.

Characteristics of Gold Nanoparticles (Fig. 2)
- Gold nanoparticles are chemically inert.
These have greater biological compatibility.
They have stability due to the gold sulphur bonds.
Their photo physical properties can be exploited for drug release at remote place.
Gold nanoparticles provide microscopic probes for study of cancer cells.

Types of Gold Nanoparticles
1. Gold nanorods
2. Gold nanoshells
3. Gold nanocages
4. Gold nanosphere
5. SERS nanoparticles

Gold Nanorods
These are synthesized by template method. These are prepared by electrochemical deposition of gold within the pores of nanoporous polycarbonate template membranes.

Gold Nanoshells
Surface plasmon resonance peaks (ranging from visible to near i.r region) is used for the designing and fabrication of gold nanoshells. The core of gold nanoshells is made up of silica and outer surface is made up of gold.

Gold Nanocages
Through galvanic replacement reaction between truncated silver nanotubes and aqueous HAuCl₄, gold nanocage is synthesized.

SERS Nanoparticles
SERS is an optical technique like fluorescence and chemiluminescence having better sensitivity, high levels of multiplexing, robustness and greater performance in load and biological.

Solid Nanosphere
These are synthesized by reduction of an aqueous hauc1₄, by using citrate as reducing agent. Through citrates/gold ratio the size of nanospheres can be affected by thiol/gold molar ratios.

Synthesis of Gold Nanoparticles
1. Initially prepared aquaregia solution which contains 3 parts of HCL and 1 part of HNO₃ which is highly corrosive and oxidizing agent.
2. Then use chloroauring acid as reactant and sodium borohydride as reducing agent. NaBH solution+Deionised water.
3. The change in colour of gold from yellow to ruby red indicates the preparation of gold nanoparticles.
4. Gold nanoparticles of 1-2 nm can be prepared by using diborane as reducing agent with phosphine as stabilising agent to prevent agglomeration. Gold nanoparticles of 10-150 nm can be prepared by using sodium citrate as reducing agent in water and citrate as stabilising agent.
5. After synthesis the other molecules replace the capping agents by ligand exchange reaction.

Functionalisation of Gold Nanoparticles
Mono layer protected clusters can be prepared by one-pot protocol drug for cancerous cells. Mixed mono layer protected cluster can be prepared directly or by murray through place exchange reaction of thiol.
Coumarin, a fluorescent dye when is conjugated with poly ethylene glycol at one end and at the other end gold nanoparticles. The effect of coumarin-PGE-thiol is increased. So due to PEG the fluorescent receptor quenching effect of gold nanoparticles is decreased.
So through PEG spacer the gold nanoparticles, in the aqueous disruption of gold nanoparticles coumarin-PGE thiol are added for conjugation. There is a covalent interaction.

Invivo targeting using gold nanoparticles. It can be done by two approaches.
1. Active targeting
2. Passive targeting
Active targeting depends on recognition of ligand on the gold nanoparticles surface by cell surface receptors.
Passive targeting depends on the extravasations of vectors through leaky blood vessels in unhealthy tissue.
- Gold nanoparticles are used to identify the protein interaction under the study of immunohistochemistry.
- Gold nanorods can be used to detect the cancer stem cells.
These are used to detect the aminoglycoside antibiotics like streptomycin, gentamycin, neomycin.

These are used as lab tracer to detect the pressure of DNA in the sample. So these are used in fingerprinting.

Applications of Nanoparticles[12]

1. Delivery of proteins, peptides and nucleic acid
2. Delivery of drugs
3. Gold nanoparticles in microbiology and science
4. Gold nanoparticles in diagnostic
5. Gold nanoparticles in therapy
6. Gold nanoparticles as drug carriers
7. Immunological properties of gold particles
8. Gold nanoparticles in clinical trails

Delivery of Proteins[13], Peptides and Nucleic Acid

These can be employed as a carrier for delivery of peptides, proteins and nucleic acids like DNA due to their tunable size. GNPS are functionalised with cationic quaternary ammonium groups can bind DNA plasmid through electrostatic interaction and protect DNA from enzymatic digestion. GNPs can work as a carrier for peptides and proteins; have reported that the Trans mucosal delivery of insulin is enhanced.

Delivery[14] of Drugs:

GNPs cause local heating when irradiated with light in 800 to 1200nm. They cause the photo thermal destruction of tumours. GNPs are used to identify protein interaction under the study of immunohistochemistry. These are used as a lab tracer to detect the presence of DNA in sample. They are used for the detection of aminoglycosides antibiotics like streptomycin, gentamycin and neomycin. Gold Nanorods can used to detect the cancer stem cells.

Gold Nanoparticles in Microbiology and Science

The application of GNPs conjugates in biochemical diagnostics[15] and analytics, photothermal and photodynamic therapies, as a carrier for delivering target molecules and on the immunological and toxicological properties.

Gold Nanoparticles in Diagnostics:

Visualisation and Bioimaging

GNPs are used in resonance scattering dark field microscopy for the detection of microbial cells and their metabolites, the bioimaging of tumour cells and for the detection of receptors on their surface, for the study of endocytosis.

Gold Nanoparticles in Therapy:

---

www.ijapbjournal.com
Photothermal Therapy using Gnp's
Photothermal cell damage is a promising direction in both tumour therapy and therapy of infectious diseases.

Photo Dynamic Therapy using Gnp's\[^{16}\]
It is applied in therapy of oncological diseases, certain dermal or infectious diseases and is based on use of photo sensitizers. The agents for photo dynamic therapy (PDT) can selectively accumulate in the tumour or other target tissues. The main drawback of PDT is that photo sensitizers remain in organism for a long period of time; as a result, the patient's tissues remain highly sensitive to light.

Gold Nanoparticles as Drug Carriers
The targeted delivery of drugs is one of the most promising and actively developing directions in the medicinal use of GNPs. Antitumour agents and antibiotics are the most popular objects of target delivery. The options of using GNP conjugated with the following antitumour agents were proposed: paclitaxel, methotrexate, sulfonamide, platinum complexes, hemcytabin etc.

Immunological Properties of Gold Nanoparticles
The physic chemical immunity theory, postulates\[^{17}\] that immunogenicity and antigenic specificity depends prominently on physic chemical properties of the compounds and on their colloidal state. Unfortunately with the development of immunology and negation of many postulates, interest towards the immunological properties of colloids has abated.

Gold Nanoparticle Clinical Trails
The national cancer institute, the US food and drug administration, the national institute of standards and technologies, performs and standardises the preclinical characterisation of nanoparticles intended for cancer therapy. Previous clinical trials of TNS-alpha demonstrated dose limiting toxicity of hypotension and nausea at 225 micrograms. Dose levels of 50-60 micrograms TNF were administered with no dose limiting toxicity observed.

Advantages and Disadvantages of Gold Nanoparticles
Advantages
1. Simple diagnosis
2. Less invasive
3. Diagnosis of oral cancer
4. Non-toxic to human beings
5. Gold is virtually indestructible, it lasts forever.
6. It is inert to all chemical, encounters in the body.

Disadvantages
1. Biocompatibility
2. Acute and chronic toxicity
3. Ability to escape reticulo endothelial system need further researches.

CONCLUSION
The use of Gold nanoparticles in cancer offers exiting possibilities such as destroying cancer tumours with minimal damage to healthy tissues and organs as well as the detection and elimination of cancer cells before they form tumours. Many efforts to improve cancer treatment through nanoparticles are at the research and developing stage. It is possible that these efforts will result in cancer becoming being nearly eliminated smallpox in the last century.
